Task # 1

Bfs search is a kind of Seach which is level by level that defines where a node is complete or not it works on a principle that first comes first go where we see the node which is come first come and then go first on the other hand DFs work as a pick one node go to the very last and pick other then go to last and soon until we find and we also say first come ast go but in it shortest part is not exactly

Task # 2

DLS works same as DFS but there are some limits and they must be done as a pick one node go to the very last and pick other then go to last and soon until we find but the condition is limit whether it will be in a loop problem

Task # 3

UCS works on the cheapest way and then give the node as want to where the sub cost is 1 and then calculate the next term
